AN-6130

HI-6130 Application Development Kit

Introduction

The Holt HI-6130 Application Development Kit demonstrates the broad feature set of the HI-6130 Multi Terminal IC for MIL-STD-1553. The 2-board assembly and C project reference design provides a ready-to-run evaluation platform demonstrating concurrent operation for any combination of Bus Controller, Bus Monitor and one or two Remote Terminals. For convenience, this kit includes IAR Systems Embedded Workbench® for ARM, and a fully integrated debug interface for the ARM Cortex M3 microcontroller.

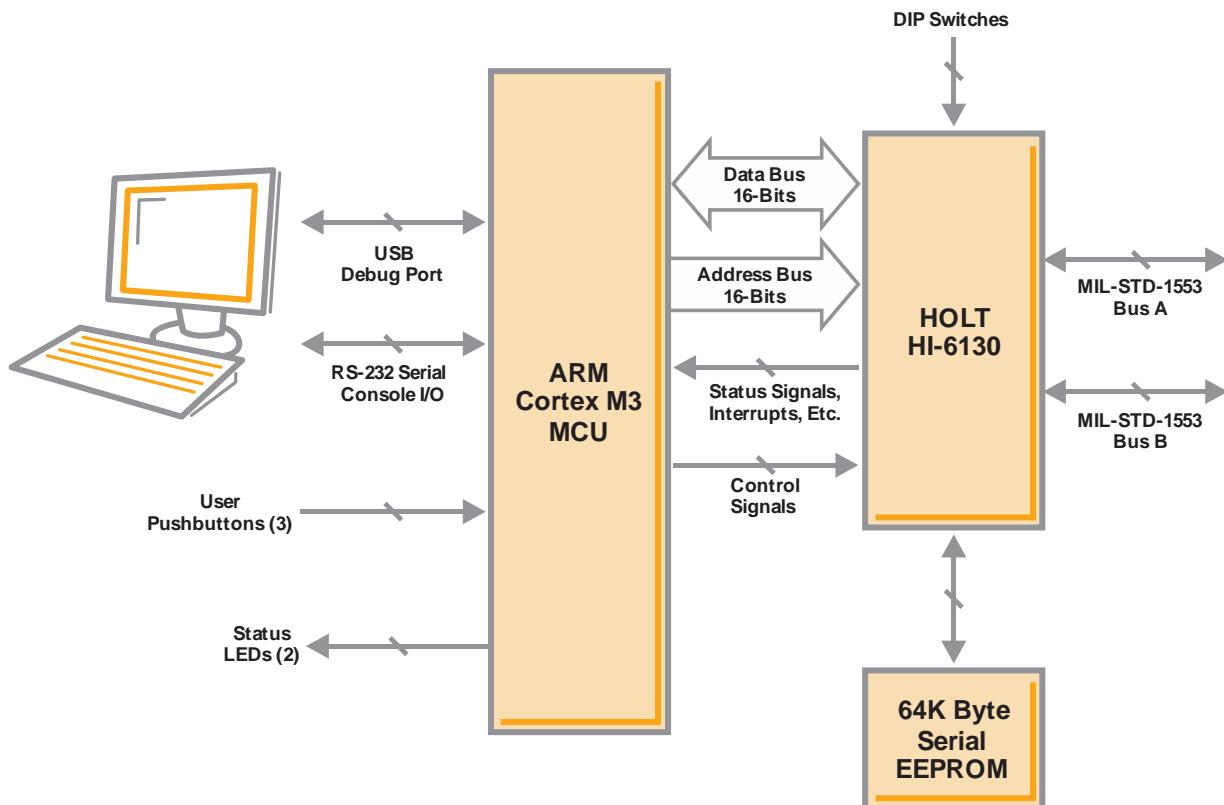

This guide describes how to set up and run the board. Additional support material and all required project software are found in the included Holt CD-ROM. A version of the demonstration software is already programmed into the microcontroller flash; the board is operational right out of the box without installing or running the provided software development tools.

Evaluation Kit Contents

- This User Guide.
- Holt HI-6130 Project Software and Documentation CD.
- Installation CD for IAR Systems Embedded Workbench® for ARM (32KB KickStart ed.).
- Plug-in DC power supply.
- USB debug interface cable.
- RS-232 serial cable, DB-9M to DB-9F for console I/O using a connected computer.
- 2-board assembly comprised of
 - Upper HI-6130 board with dual transformer-coupled MIL-STD-1553 bus interfaces. Numerous DIP switches configure board operation.
 - Lower MCU board with ARM Cortex M3 16-/32-bit microprocessor, debug interface and regulated 3.3VDC power supply.

Hardware Block Diagram

Hardware Design Overview

Refer to the end of this guide for separate schematic diagrams and bills of material for the upper and lower circuit boards.

The detachable HI-6130 board can be separated from the provided MCU board for connection to a user-supplied alternate microprocessor or FPGA board. The inter-board headers are located on 0.1" (2.54 mm) grid for compatibility with generic prototyping boards. All host interface signals go through the inter-board headers. Numerous HI-6130 configuration pins (and the Remote Terminal address setting pins) are controlled by DIP switches on the upper HI-6130 board; these signals are not available on the inter-board headers.

The lower ARM Cortex M3 board is based on the flash-programmable Atmel AT91SAM3U-EK microprocessor. A 16-bit parallel bus interface connects to the HI-6130. A UART-based serial port provides RS-232 console I/O (optional). An uncommitted USB 2.0 port is available for future expansion. Two pushbuttons are available for software interaction. A RESET pushbutton resets the ARM microprocessor, which in turn controls the HI-6130 Master Reset signal.

The ARM Cortex M3 board includes "J-Link On Board" debug interface, licensed from www.segger.com, providing out-of-box readiness without having to buy a costly JTAG debug cable. The kit includes a simple USB cable for connecting the board's debug interface to your computer. (For users already owning an ARM debug interface with ribbon-cable connector, an ARM-standard 2x10 debug connector provides debug connectivity. In this case, jumper JP2 on the bottom of the lower board should be soldered closed to disable "J-Link On Board".)

New In This Version

Both demo programs, Holt HI-6130-40 EBI Demo 2.0 and Holt HI-6130 Simple RT V 1.0 are updated to versions 2.1 and 1.01 respectively. Both programs were modified to run from IAR's recommended "my documents" path. Previously, IAR projects were installed in C:\Program Files\IAR Systems\...\at91sam3u-ek. IAR EWARM version 7.1 was used to compile these demo programs. Normally newer versions of IAR don't have an issue opening older projects. We recommend IAR EWARM 7.1 or newer for new Holt projects. To convert an older project to use "my documents/..." path, see the included document "Holt Technical Note - IAR Demo Project Installation" contained on the CD ROM.

The newer demo program, HI-6130 Simple RT is the default demo program flashed into the Atmel Cortex M3 microcontroller. This program demonstrates more features of the HI-6130 and displays RT traffic data on the console. The Simple RT demo is fully described in the AN-6130DG design guide with step-by-step instructions how to initialize RT1. The other demo program is available on the Holt CD ROM.

A Quick Demonstration

The Holt HI-6130 Application Development Kit is pre-programmed to concurrently operate as a Bus Controller, SMT Bus Monitor and two independent Remote Terminals. Terminal addresses for the two RTs are preset using DIP switches, before applying power. RT addresses 3 and 4 are utilized by the preprogrammed Bus Controller message repertoire. The two 6-position DIP switches should already be set with these address values, plus odd parity. All the default DIP switch settings are shown on the board photo on page 1 of this document.

1. To observe bus activity, connect an oscilloscope to the red BUS A and red BUS B test points. The test point labeled ACTIVE is a convenient scope trigger signal.
2. If not connected by cable to MIL-STD-1553 buses, provide a dummy load for buses A and B by connecting a 70Ω 1/2 Watt resistor across each pair of red and black Bus test points. (For this demonstration, half-Watt resistors are adequate because duty cycle is sufficiently low.)
3. The preprogrammed demonstration provides console I/O between the MCU board serial port and a Windows computer running a terminal emulation program. Using the provided DB-9 serial cable, connect the MCU board to the serial port on the Windows computer. If using XP or Windows 2000, open HyperTerminal from the Windows “Accessories” program group. If using Vista or Windows 7, install TeraTerm (see page 5) and run it. Configure the terminal program for 115,200 baud, no parity, 8 data bits, 1 stop bit, flow control off. If configured correctly, a text header appears when power is applied, or when the RESET pushbutton is pressed.
4. Plug-in the provided 5V DC power supply and connect the cable to the power input jack on the lower circuit board. The command menu should appear in the HyperTerminal window.
5. The Bus Controller is programmed to execute a repeating series of MIL-STD-1553 commands to Remote Terminal addresses 3 and 4. Each bus command is preceded by a BC “Wait for Trigger” op code. The MCU is preprogrammed to issue a trigger pulse to the BC each time the numeric “1” key is pressed on the computer keyboard. (By turning off the console I/O option and recompiling the program, the Bus Controller can be paced instead by pressing the SW1 button on the MCU board, but the TeraTerm console output will be disabled in this mode.)
6. Each time the numeric “1” key is pressed on the computer keyboard, a new Bus Controller command is issued to RT address 3 or RT address 4 (or both RT addresses 3 and 4, in the case of RT-RT messages). The Remote Terminal responses can be observed, and the TeraTerm console screen reports new message results for each key press.

7. New in this demo program, the Simple RT portion of the demo displays RT traffic data on the console. A receive command to RT1 to SA1 will flash a green or orange LED on the board depending on the contents of the first data word. See AN-6130DG for details, usage and data traffic console output examples.

Getting Started With Full Evaluation

The following steps install and configure the C compiler and describe how to load and modify demonstration projects using the HI-6130 Application Development Kit.

1. Using installation defaults, install IAR Embedded Workbench® for ARM EWARM onto your Windows computer. Embedded Workbench for ARM is a fully functional integrated development environment including project manager, editor, compiler, assembler, linker, librarian and debugger tools. It includes an optimizing C compiler, and supports a wide range of ARM devices and hardware debug systems. Ready-made device configuration files, flash loaders and example projects are included. The kit's installation CD is for the KickStart edition of IAR Embedded Workbench®. You must register at the IAR website to obtain a license file for Embedded Workbench®. The license is permanent; its only limitation is program size. If your compiled program exceeds 32K bytes, try disabling the console I/O option (in project file **613x_config.h**). This significantly reduces compiled program size without compromising MIL-STD-1553 functionality. Otherwise, a 30 day evaluation license for the unrestricted version of Embedded Workbench for ARM is available at IAR web site, www.iar.com. Refer to IAR's Released Notes in section "Important Information" for more installation information.

NOTE: Windows Vista and Windows 7 have a new security mechanism called UAC (User Access Control). Disabling UAC will make Vista/7 work more like XP. This is necessary to run IAR Embedded Workbench as administrator. This was important when demo projects were installed in Program Files\...\ but it is not needed when demo programs are installed in the “my documents path”. This is here for reference.

Execute the following steps to disable UCS.

- i) Control Panel-> User accounts and Family Safety.
ii) User Accounts -> Change Users Account Control Settings
iii) Set the control to -> never modify.
iv) Reboot
2. If using console I/O (recommended for initial evaluation, your computer needs a serial (COM) port and a “terminal emulation” program like TeraTerm. Most desktop computers have a COM port; many notebook computers do not have a COM port; these require a serial-to-USB adapter.

If using Windows 2000 or Windows XP, you can use HyperTerminal for terminal emulation. Open HyperTerminal by clicking **Start** then **All Programs**; click the Windows **Accessories** then **Communications** program group. Double-click HyperTerminal to run it. Skip the next paragraph.

If using Vista or Windows or later.

HyperTerminal is not included with these versions of Windows. Install the free open-source terminal emulation program, *TeraTerm 4.71*, by running the provided teraterm-4.71.exe installer program from the Holt CD. Accept the license agreement stating redistribution is permitted provided that copyright notice is retained. The notice can be displayed from the TeraTerm window by clicking **Help** then clicking **About TeraTerm**. Continuing to install...

- Accept the default install destination and click **Next**.
- At the Select Components screen, unselect all options except Additional Plugin = TTXResizeMenu and click **Next**.
- Select the installed language, then click **Next**.
- Accept the default Start Menu folder, then click **Next**.
- Select any desired shortcuts, then click **Next**.
- At the Ready to Install screen, click **Install**.

Run the TeraTerm program. At the **New Connection** screen, select **(x)Serial** and choose the selected COM port. Click **Setup** then **Serial Port** to open the serial port setup window. Choose these settings: Baud Rate: 115200, Data: 8 bits, Parity: none, Stop: 1 bit, Flow Control: none. Using the provided DB-9 serial cable, connect the MCU board to the computer serial (COM) port.

3. Plug-in the provided 5V DC power supply and connect the cable to the power input jack on the lower circuit board. If TeraTerm is running and configured correctly, the command menu below should appear in the console window. This menu appears whenever board power is applied, or After verifying correct TeraTerm communication with the evaluation board, the terminal set up can be saved by clicking **Setup** then **Save Setup**.

AN-6130

The screenshot shows a terminal window titled "COM1:115200baud - Tera Term VT". The window has a menu bar with File, Edit, Setup, Control, Window, and Help. The main text area displays the following information:

```
Holt Integrated Circuits HI-6130 Simple Terminal Ver: 1.01
Compiled: Jan 23 2015 08:30:29

Host is Initializing Regs & RAM

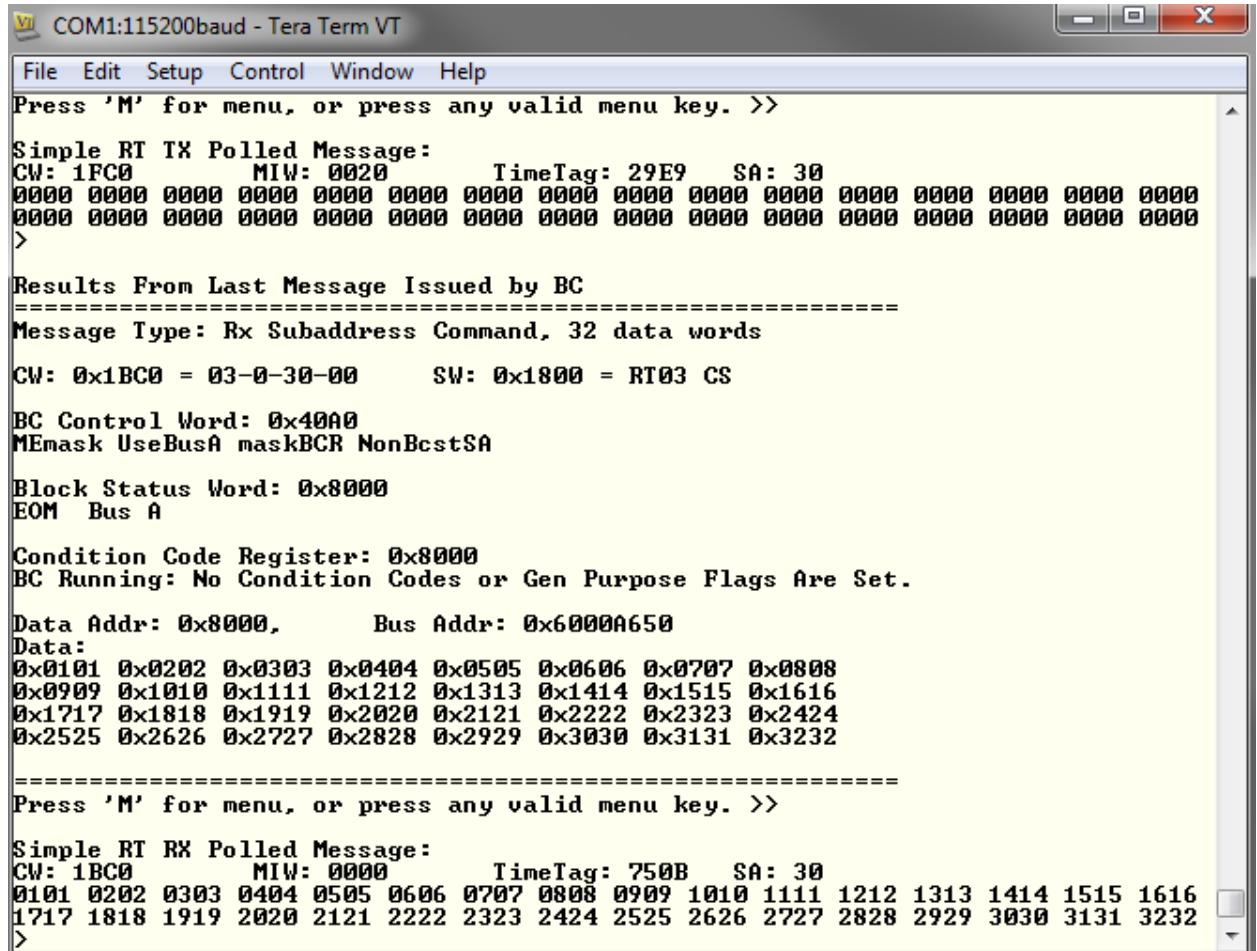

*****
Holt Integrated Circuits HI-6130 Simple Terminal V 1.01
Compiled: Jan 23 2015 08:30:28
*****

BC On     SMT On      RT1 On      RT2 On

Press '1' to step BC and list results...
Press '2' to list BC configuration...
Press '3' to list BC condition codes & GP flags...
Press '4' to list MT configuration...
Press '5' to list MT results, last msg...
Press '6' to list HW interrupt status...
Press '7' to list BC interrupt status...
Press '8' to list RT interrupt status...
Press '9' to list MT interrupt status...
NOTE: Options 6-9 clear the accessed Pending Interrupt Register
!

=====
Press 'M' for menu, or press any valid menu key. >>
```

The following shows the console screen, after pressing '1' three times on the keyboard from the previous menu. The BC transmits CW = 0x0BC0 (command word) and shows the data transmitted. The Simple RT receives this command and data and displays the traffic message type, MIW, TimeTag, Subaddress and number of data words received. The HI-6130 BUS A output connector should be terminated with a 75 ohm termination resistor or connected to a MIL-STD 1553 bus coupler for the Simple RT to reliably receive the command and data.

COM1:115200baud - Tera Term VT

4. Debug requires an interface between the computer running IAR Embedded Workbench® and the HI-6130 Application Development Kit. Connect the small end of the provided USB cable to the HI-6130 evaluation board USB connector marked DEBUG. Connect the other end of the USB cable to a free computer USB port. The IAR C-SPY Debugger for ARM includes drivers for numerous target system interfaces, including built in “J-link On Board”.

The first time the evaluation board USB cable is connected to the computer, the Windows “Found New Hardware” message should appear for the J-Link device. After several seconds, Windows should load the appropriate driver and advise, “Your hardware is ready for use”. If Windows fails to find the J-Link driver, direct it to look in the Drivers directory the IAR Embedded Workbench® installation CD.

If difficulties arise when initiating a debug session at step 11, click **Project** then **Options**. In the window that opens, under **Category = Debugger** highlight **J-Link/J-Trace**. Click the tab labeled **Connection**, then verify Communications = USB and Interface = SWD.

5. The Holt CD provided contains one or more example MIL-STD-1553 projects written in ANSI C. Examine the CD's PROJECTS directory to determine which project best meets your requirements. The entire project folder (or subdirectory) should be copied to a specific location on your computer's hard drive.
6. Install IAR Embedded WorkBench® from the included IAR CD ROM. Refer to document "Holt Demo Project Installation for IAR Systems". Once installation is complete and at least one Atmel sample project is installed copy the Holt zipped projects somewhere on the PC and unzip the two projects.
7. Move the entire **_Holt** project folder into this location:
C:\My Document\IAR embedded workbench\Atmel\atmel\at91sam3u-ek
Do not install it in the old location below:
C:\Program Files\IAR Systems\Embedded Workbench 6.xx\arm\examples\Atmel\at91sam3u-ek
8. Open IAR Embedded Workbench®. Click **File**, then **Open Workspace**, then navigate to the project subdirectory created in step 5. Select the project file with .EWW extension, then click **Open**. (The next time Embedded Workbench® opens, this project will appear in the Recent Workspaces list when **File** is clicked.)
9. If problems occur with IAR installation or with using the IAR debugger, two Holt technical notes are provided to help resolve these issues included on the Holt CD ROM.
10. The HI-6130 project only uses unsigned integer variables. Turn off the nuisance compiler message that occurs when a variable's most significant bit toggles. The message looks like this:
Remark[Pe068]: integer conversion resulted in a change of sign
To disable this diagnostic message, click **Project** then click **Options**
Category = C/C++ Compiler
Tab = Diagnostics
Suppress these diagnostics: add "Pe068" to list
11. The Holt IAR project includes seven predefined configurations which can be selected from the workspace pull-down menu. The configurations modify the preprocessor labels BC_ena, RT1_ena, RT2_ena, SMT_ena and IMT_ena. These are compile time labels used by the compiler to customize the builds.

The default configuration BC_MT_RT enables the primary modes BC, MT, RT1 and RT2 in the HI-613X device. This is the default configuration programmed into the demo board. This enables and demonstrates the Bus Controller, RT1 and RT2 Remote Terminals and a Monitor. These configurations are all flash based projects. RAM based projects are not supported due to the limited amount of RAM on the MCU. By design the Cortex™-M3 runs slower in RAM than in

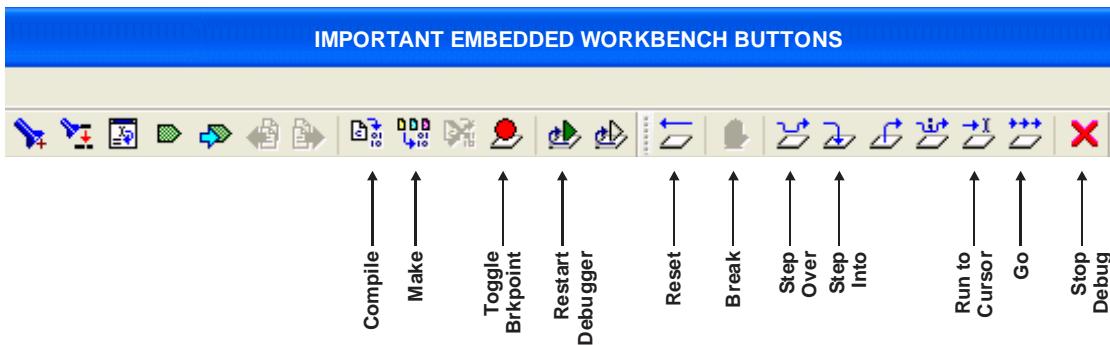

Flash so there is little need for a RAM based project. The seven configurations and the corresponding preprocessor label values are provided in the table below:

Configuration	BC_ena	RT1_ena	RT2_ena	SMT_ena	IMT_ena
BC_MT_RT (default)	1	1	1	1	0
BC_ONLY	1	0	0	0	0
SMT_ONLY	0	0	0	1	0
RT_ONLY	0	1	1	0	0
IMT_ONLY	0	0	0	1	0
RT_SMT	0	1	1	1	0
RT_IMT	0	1	1	0	1

Other configurations are possible except just one type of Monitor can be selected at a time, so SMT_ena and IMT_ena cannot both be enabled (set to 1). A simple way to create a new configuration is to select Project/Edit Configurations and then select New. The dialog box will allow a new configuration based on an existing configuration with a new configuration name. Select the new configuration and edit the preprocessor labels as desired then save the new configuration. The new configuration will now appear in the pull down menu.

When changing the configurations from the default the corresponding four terminal DIP switches on the board BCENA, MTRUN, RT1ENA and RT2ENA should be set to match. If any of these do not match an error will be displayed on the console when the board first powers up.

12. Project file 613x_initialization.h configures other critical project settings, including the time tag resolution and console I/O on-off.
13. Compile the project by clicking the **Make** button. See following illustration. If the Build messages window in IAR Embedded Workbench® indicates no errors or warnings, you can continue. If errors occurred, correct them and recompile the program. Holt projects in zipped format may exclude *.o and *.lst files, this significantly reduces project file size which makes it much easier to provide them by email.
14. Initiate a debug session by clicking the **Restart Debugger** button. This downloads the compiled program into the MCU and readies the board for program execution. Click **Go** to start execution. Click **Break** (normally displayed during execution as a red upheld hand) to stop execution.

15. To program the auto-initialization serial EEPROM with a new configuration:

- Before starting program execution, turn off the DIP switch labeled AUTOEN, directing the MCU to initialize the HI-6130 instead of using self-initialization from the EEPROM. Turn on the DIP switch labeled COPYREQ, directing the MCU to initiate the EEPROM copy sequence after post-reset initialization of HI-6130 registers and RAM is complete.
- When execution starts, the red LED illuminates during the EEPROM copy process. When it turns off, turn on the DIP switch labeled AUTOEN to reactivate self-initialization. Turn off the COPYREQ DIP switch, preventing EEPROM rewrite at each reset.

16. To observe bus activity, connect an oscilloscope to the red BUS A and red BUS B test points. The test point labeled ACTIVE is a convenient scope trigger signal. If not connected by cable to MIL-STD-1553 buses, provide a dummy loads for buses A and B by connecting a 70Ω 1 Watt resistor across each pair of red and black Bus test points.

Project File List with Selected Descriptions

HEADER FILES WITHOUT CORRESPONDING C FILES

613x_initialization.h

definitions for important configuration settings

device_6130.h

ARM MCU external bus interface definitions
structs for register addressing, HI- 6130 only

613x_regs.h

Macros for register bits and bit fields

C FILES WITH CORRESPONDING HEADER FILES

Most of the function names are self-explanatory.

main.c

```
main(void);
```

The primary program entry portal, main() demonstrates the initialization sequence used, whether or not self-initialization from EEPROM is enabled, for any combination of enabled terminals. After initialization is complete, function calls demonstrate powerful addressing methods for all RAM structures used by the enabled terminal modes.

board_613x.c

```
ConfigureGpio(void);
```

This function initializes ARM MCU general purpose I/O

```
reset_613x(void);
```

```
char autoinit_check(void);
```

```
initialize_613x_shared(void);
```

```
init_timer(void);
```

```
Delay_us(unsigned short int num_us);
```

```
Delay_ms(unsigned short int num_ms);
```

```
Delay_Nx100ms(char num);
```

```
error_trap(char count);
```

board_6130.c

```
Configure_6130_EBI(void);
```

This function initializes ARM MCU external bus interface

613x_BC.c

```
void BC_bus_addressing_examples(void);
```

```
initialize_bc_msg_blocks(void);
```

```
initialize_bc_instruction_list(void);
```

```
initialize_613x_BC(void);
```

```
bc_disable(void);
```

```
bc_enable(void);
```

```
bc_start(void);
```

```
bc_trigger(void);
```

```
SW1_BC_Trig_Test(void);
```

For the demo, this function polls pushbutton SW1 and triggers next BC message when pressed

613x_MT.c

```
initialize_613x_MT(void);
```

This function initializes either simple or IRIG-106 (SMT or IMT) monitor operation

613x_RT.c

```
initialize_613x_RT1(void);
```

```
initialize_613x_RT2(void);
```

```
RTAddr_okay(char RTnum);
```

```
modify_RT_status_bits(void);
```

```
write_dummy_tx_data_RT1(void);
```

```
write_dummy_tx_data_RT2(void);
```

The last two functions initialize RT1 and RT2 transmit data buffers for the demo

613x.Driver.c

New low level support code for the Simple RT traffic demo.

console.c

Console functions used by all terminal modes:

```
void ConfigureUsart1(void);
void text_header(void);
void chk_key_input(void);
unsigned short int list_hw_ints_console(void);
```

Console functions used by Bus Controller (BC) mode:

```
void bc_last_msg_console(void);
void list_bc_config (void);
void list_bc_ccgpf_reg(void);
unsigned short int list_bc_ints_console(void);
```

Console functions used by Remote Terminal RT1 and/or RT2:

```
unsigned short int list_rt_ints_console(void);
```

Console functions used by SMT or IMT bus monitor modes:

```
void list_mt_config(void);
void mt_last_msg_console(void);
unsigned short int list_mt_ints_console(void);
```

Primitive console functions that "printf" redundant char strings to reduce program size:

```
void print_null(void);
void print_splsp(void);
void print_b1sp(void);
void print_b0sp(void);
void print_dddn(void);
void print_dd0n(void);
void print_dd1n(void);
void print_menuprompt(void);
void print_line(void);
```

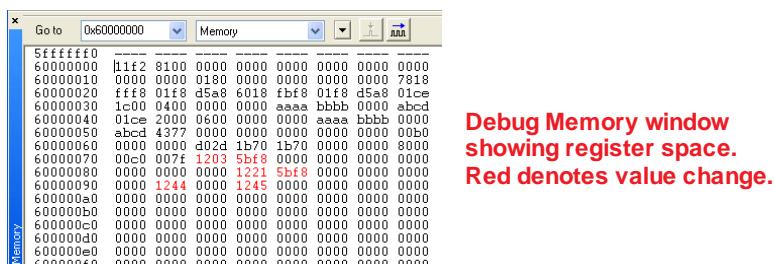

Application Development Kit Notes

The current revision for the HI-6130 data sheet can be found at www.holtic.com. Primary project configuration settings are found in the file **613x_initialization.h**.

The HI-6130 was designed for compatibility with microcontrollers having an external bus interface. RAM and register locations appear in the memory address space of the ARM Cortex M3 microprocessor on the MCU board. The utilized MCU chip select output (connected to the HI-6130 chip enable input pin) accesses a memory region starting at MCU bus address 0x60000000. Byte addressing is used. RAM and register operations transact 16-bit values, so all access addresses are even. To use byte addressing, HI-6130 RAM or register addresses are doubled and then added to the MCU chip select base address. Therefore, HI-6130 Register 0 is accessed at MCU bus address 0x60000000. Register 1 is accessed at bus address 0x60000002, and Register 5 is accessed at address 0x6000000A.

The evaluation board program provides comprehensive bus addressing examples for the fixed-address and relocatable RAM structures used by each of the MIL-STD-1553 terminal modes: BC, RT or monitor.

When using the Debugger, a Memory window may be helpful for observing register or RAM values, updated each time program execution stops. Be mindful that each displayed location is rescanned when execution stops. Some register or RAM structure bits automatically reset after read occurs. This includes bits in the Pending Interrupt registers, and DBAC Data Block Accessed bits for RT Descriptor Table Control Words in RAM. For these, the Memory Watch window reflects the value in effect when execution stopped.

When using the Debugger, a Watch window may be helpful for observing values contained in the various defined RAM structures for enabled MIL-STD-1553 modes, updated each time program execution stops. When debugging, IAR Embedded Workbench® allows up to 4 Watch windows, so separate Watch tabs can be set up for BC, RT1, RT2, etc. For each structure of interest, double-click the struct pointer name to highlight it, then drag and drop the highlighted pointer name into an open Watch window, where it can be examined. Be mindful that some RAM structure bits automatically reset after read occurs. This includes the DBAC Data Block Accessed bits for RT Descriptor Table Control Words. For these, the Memory Watch window reflects the value in effect when execution stopped.

The screenshot shows a debugger interface with two windows. The top window is a memory dump showing memory locations from 0x6130_0000 to 0x6130_001F. The bottom window is a Watch window titled 'Watch 1' containing numerous struct pointers. A red arrow points from the highlighted pointer in the memory dump to the corresponding entry in the Watch window.

The console I/O option using TeraTerm includes several menu options that read and display Pending Interrupt register status. Remember that Pending Interrupt bits automatically reset after read occurs. For these registers, the Memory Watch window reflects the value in effect when execution stopped.

The HI-6130 circuit board has two separate serial EEPROMs for auto-initialization. Selectable by a small slide switch SW2 on the upper board (may be on board's bottom side), the DEMO EEPROM is preprogrammed, while the USER EEPROM is shipped unprogrammed. By using SW2 to select the USER EEPROM, experimental project builds can be tried without overwriting the demonstration program in the DEMO EEPROM.

When debugging the IRIG-106 (IMT) Bus Monitor, at times it may be advantageous to disable the Time Tag clock to prevent packet finalization caused by attainment of "maximum recording time." For example, the BC issues a new MIL-STD-1553 command. Using a debugger Memory or Watch window, you wish to examine stored message data before triggering the BC to issue the next command. With the time tag clock running, there is no way a user can examine stored message data without exceeding maximum packet recording time. With time tag clock disabled, a series of messages can be individually issued and checked without packet finalization.

Choosing HI-6130 or HI-6131

The trade-offs...

The HI-6130 features a 16-bit parallel bus interface to the host MCU or FPGA. Its 100-pin plastic QFP package is 16 mm x 16 mm. The HI-6130 signal interface, including bus control signals and chip select, totals 36 pins. The external bus interface in the companion MCU or FPGA also increases its pin count and package size, and increases signal routing area on the circuit board.

In comparison, the HI-6131 features a four wire Serial Peripheral Interface (SPI) to the host MCU or FPGA. It is offered in a 12 mm x 12 mm plastic QFP, or 9 mm x 9 mm chip scale package. Having 32 fewer signals to connect, circuit board area is smaller than the area needed for the HI-6130. If device selection is based solely on pin count and circuit board area for signal routing, the HI-6131 is the apparent winner, but do not make a hasty decision without considering the performance differences.

The HI-6130 bus interface reads or writes one word at a time, with a cycle time of 150 ns. Reads and writes are random access, and can occur in any order. To speed up a multiword read sequences from sequential addresses, the HI-6130 automatically pre-fetches the following RAM or register location after each single-word read cycle. When reading sequential addresses, the device asserts WAIT while fetching the first data location, then all sequential address (pre-fetched) reads that follow are faster, performed without asserting WAIT.

The HI-6131 data transfer speed depends on the SPI clock frequency provided by the MCU SPI interface. When the SPI is clocked at the maximum SCK frequency, 20 MHz, each word is transferred in 800 ns, plus the overhead associated with SPI op code execution. The maximum SCK frequency for many MCUs is 15 MHz, resulting in a 16-bit word transfer time of 1,067 ns, plus op code execution overhead.

A HI-6131 Memory Address Pointer (register) is initialized by the MCU or FPGA before a read or write operation begins. The read/write operation is then initiated using an 8-bit SPI op code, serially shifted into the HI-6131 SPI by the MCU or FPGA. The host then continues clocking SCK in 16-clock multiples to read or write successive RAM or register addresses. As long as clocking continues, successive addresses are read or written. Potential problems occur when interrupts are enabled during this process. If the program's interrupt handler seizes the SPI bus to service the interrupt, it potentially disrupts an unfinished multiword transfer. Without proper software design, a simple return-from-interrupt results in a broken multiword transfer because the hardware doesn't know that an interrupt occurred and the Memory Address Pointer may or may not contain the RAM or register address for the next location in the interrupted multiword transfer.

During HI-6131 SPI transfers, interrupts must be disabled. The simplest implementation disables interrupts before sending the op code, then re-enables interrupts after reading or writing the last word in the multiword transfer. If this causes unacceptable interrupt latency, some careful software design is needed. With suitable precautions, interrupts can be momentarily re-enabled then immediately disabled between SPI words. A pending interrupt that occurred during the interrupt-off interval will be immediately recognized when interrupts are re-enabled. The pending interrupt's service routine will execute; the return-from-interrupt will jump to and execute the following "disable interrupt" statement.

The example HI-6131 software successfully completes an interrupted multiword sequence by using a "SPI interrupt occurred" flag, tested each time interrupts are momentarily disabled then re-enabled

between SPI words. Upon detection of interrupt servicing between words, the program re-initializes the memory address pointer for the next word, then re-issues the original op code to resume the interrupted multiword transfer. This approach works but requires diligence when compared to the carefree interrupt behavior of the HI-6130.

The last issue when choosing between HI-6130 and HI-6131 is ease of debug when using IAR Embedded Workbench®. Because HI-6130 registers and RAM are memory-mapped, a debugger Memory window displays data for a range of addresses, which automatically updates each time program execution stops. Changed data values are displayed in red. The HI-6130 design example defines pointer-referenced C structures (structs) which simplify addressing of the various BC, RT and monitor RAM tables and other structures. The defined C structs allow use of debugger Watch windows for observing register or RAM table data, updated each time program execution stops.

When using the HI-6131, SPI access is incompatible with C structures for table addressing. Register/RAM inspection tools comparable to the HI-6130 debugger Watch window are unavailable when using the HI-6131. Instead a utility function must be written in C to read a range of addresses, and format the data for display using console I/O or some other display means.

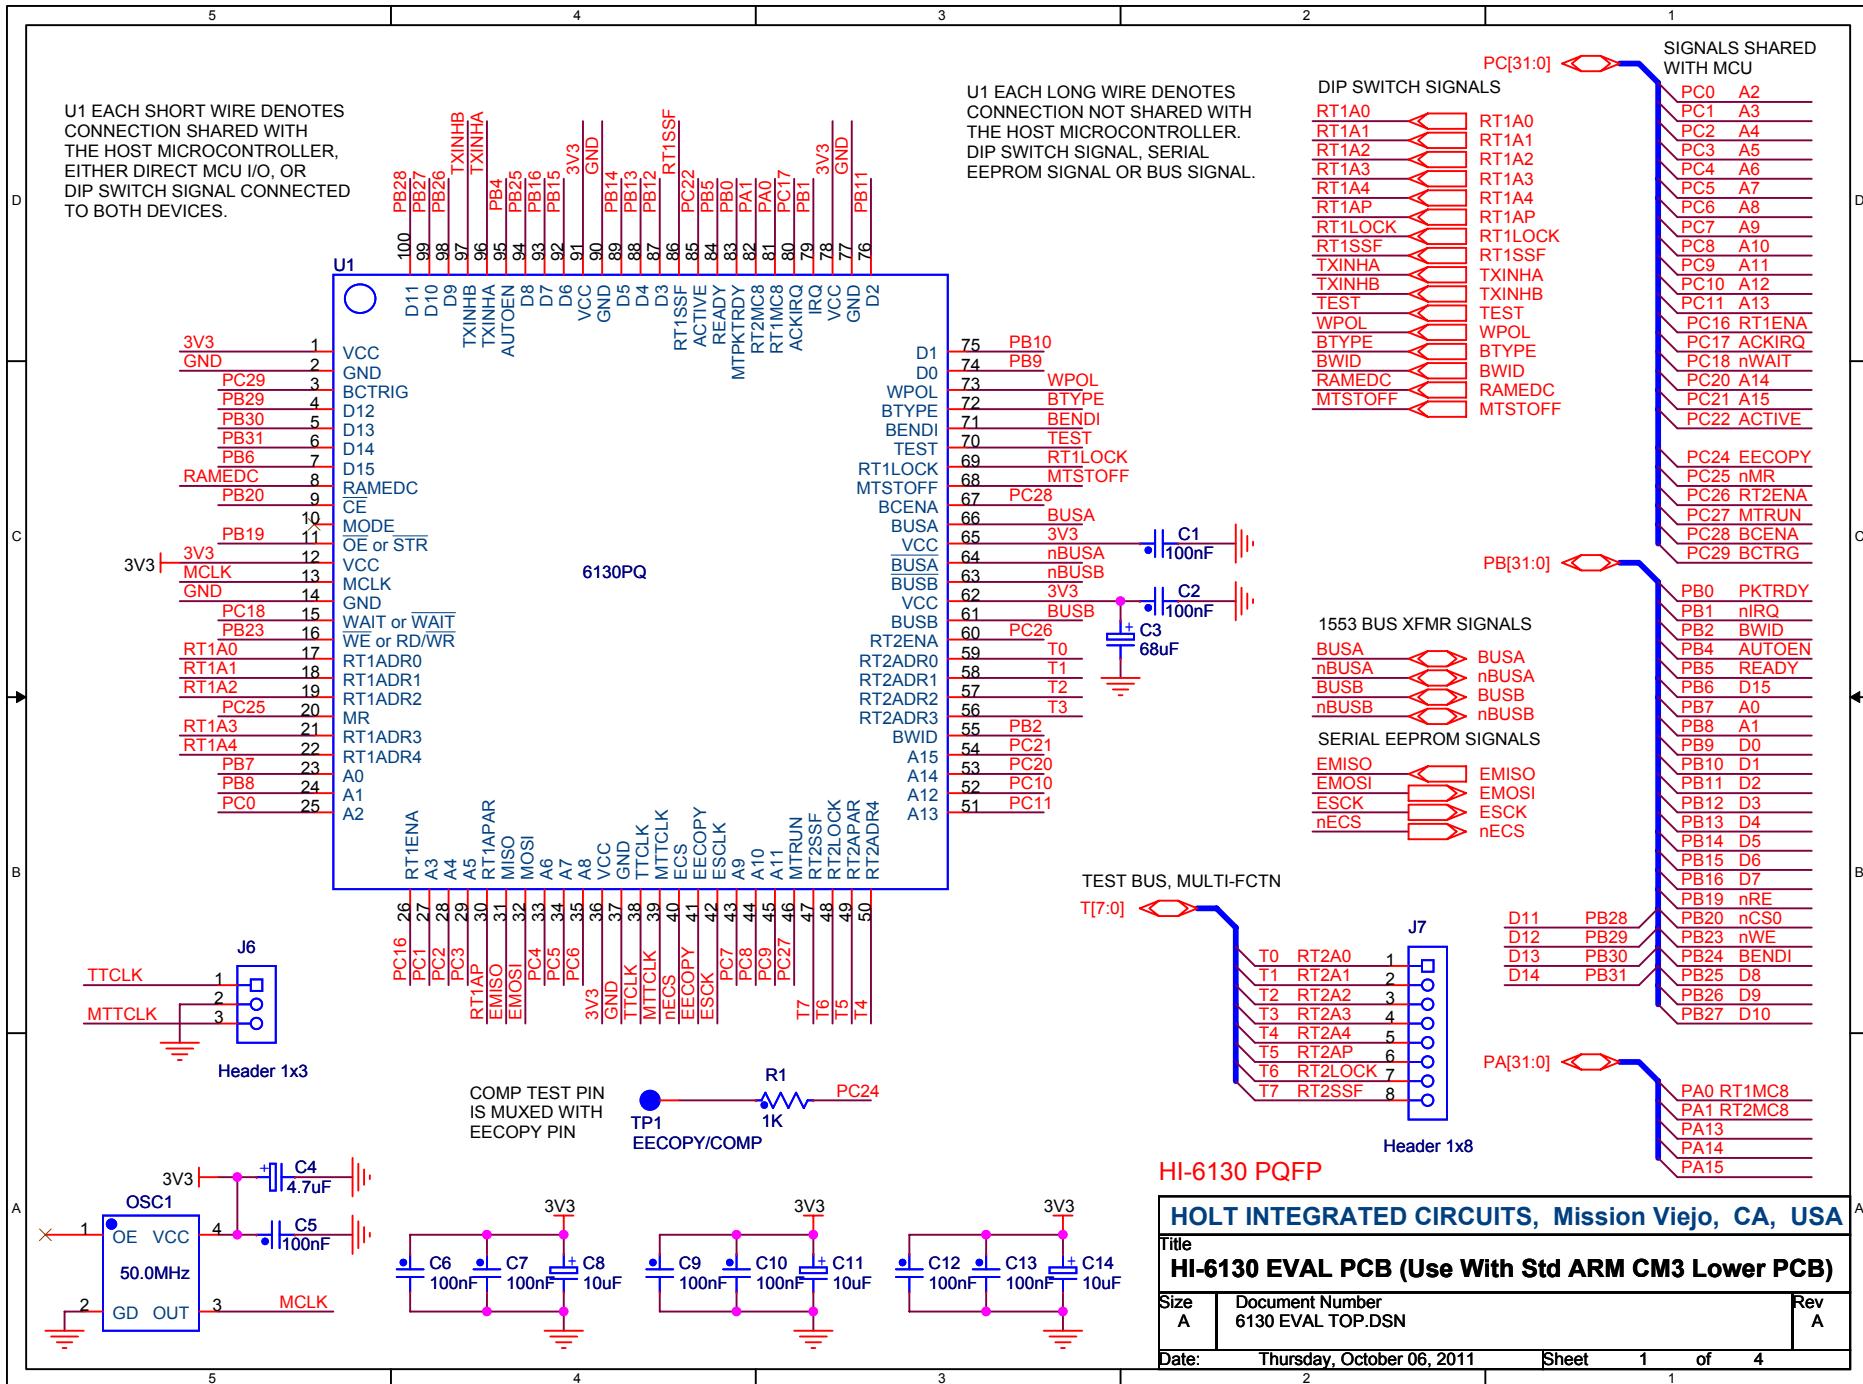

In summary...

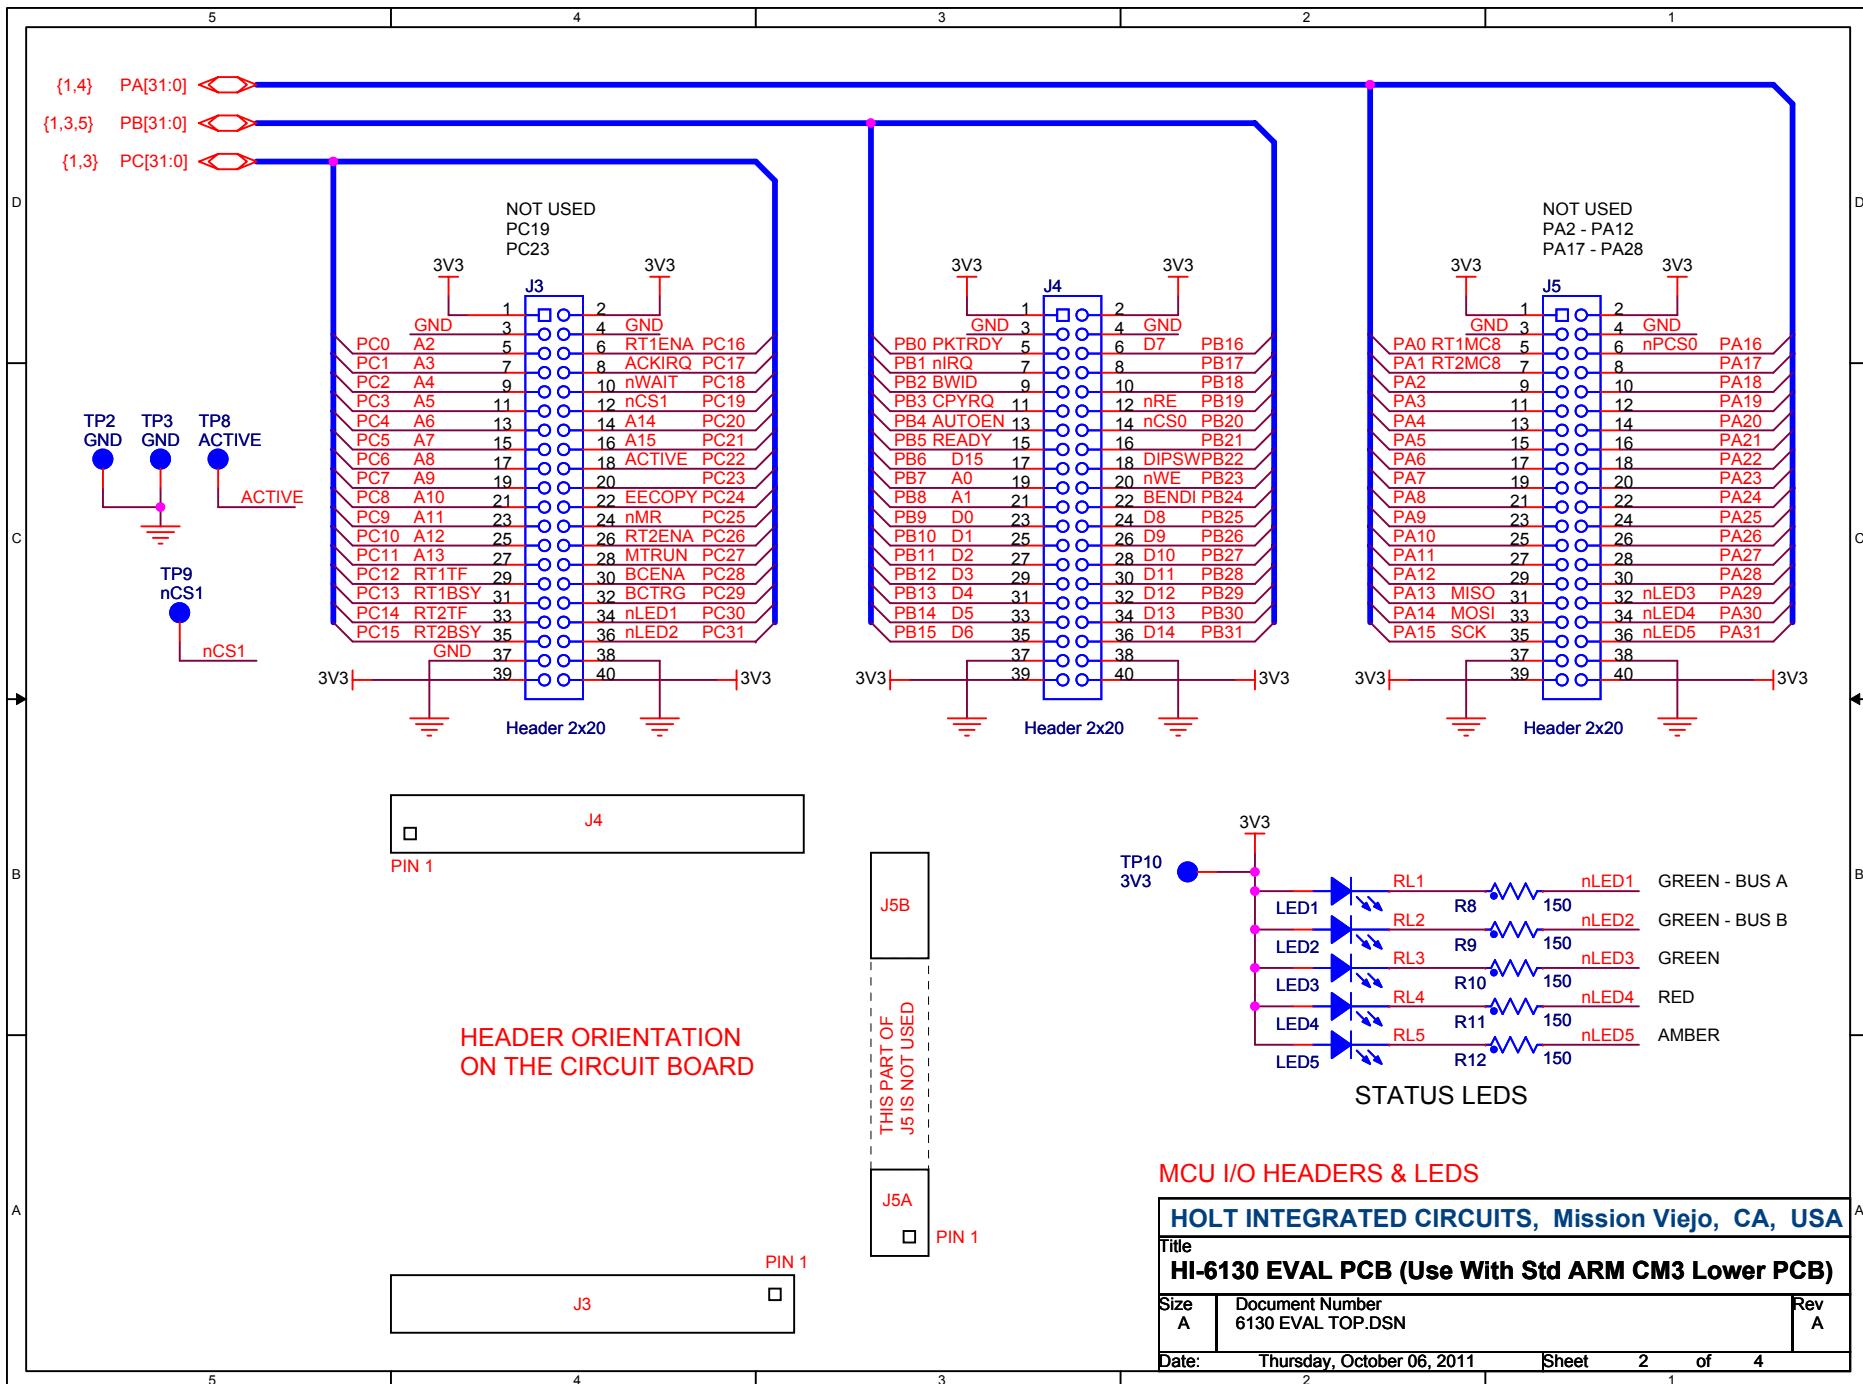

With just 4 host interface signals for accessing RAM or registers, the HI-6131 SPI interface simplifies hardware design. This advantage is offset by the need for carefully-designed interrupt handling software, and the lack of prepackaged register/RAM inspection tools when debugging.

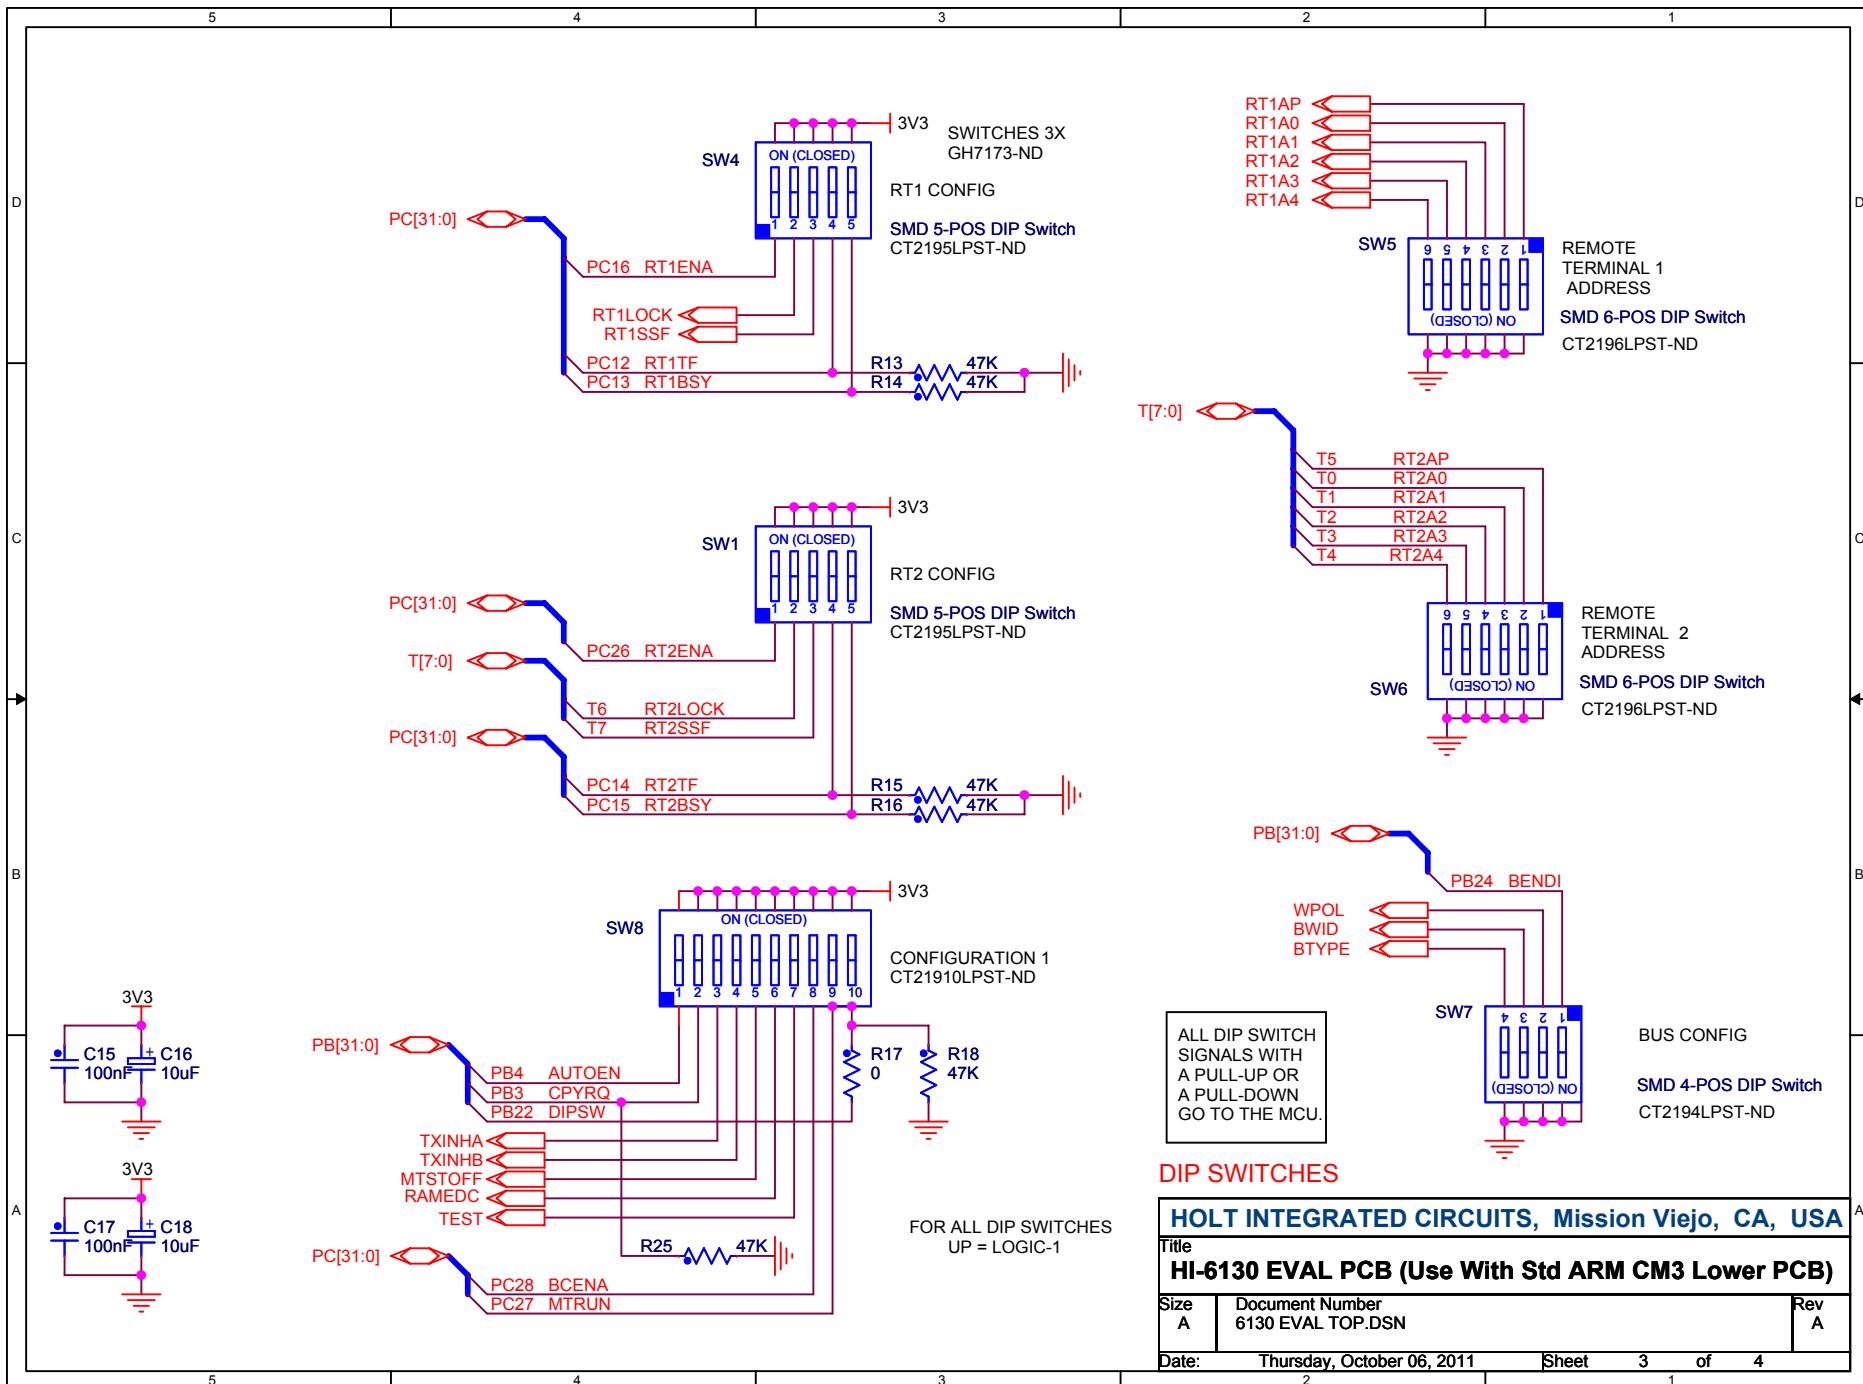

In contrast, the HI-6130 bus interface provides higher-speed random access, programming ease and powerful debugger tools. These advantages are offset by the need to connect 36 interface signals for accessing RAM or registers. Compared to the HI-6131, two additional 16-bit wide buses (address and data) must be connected between the HI-6130 and its host MCU.

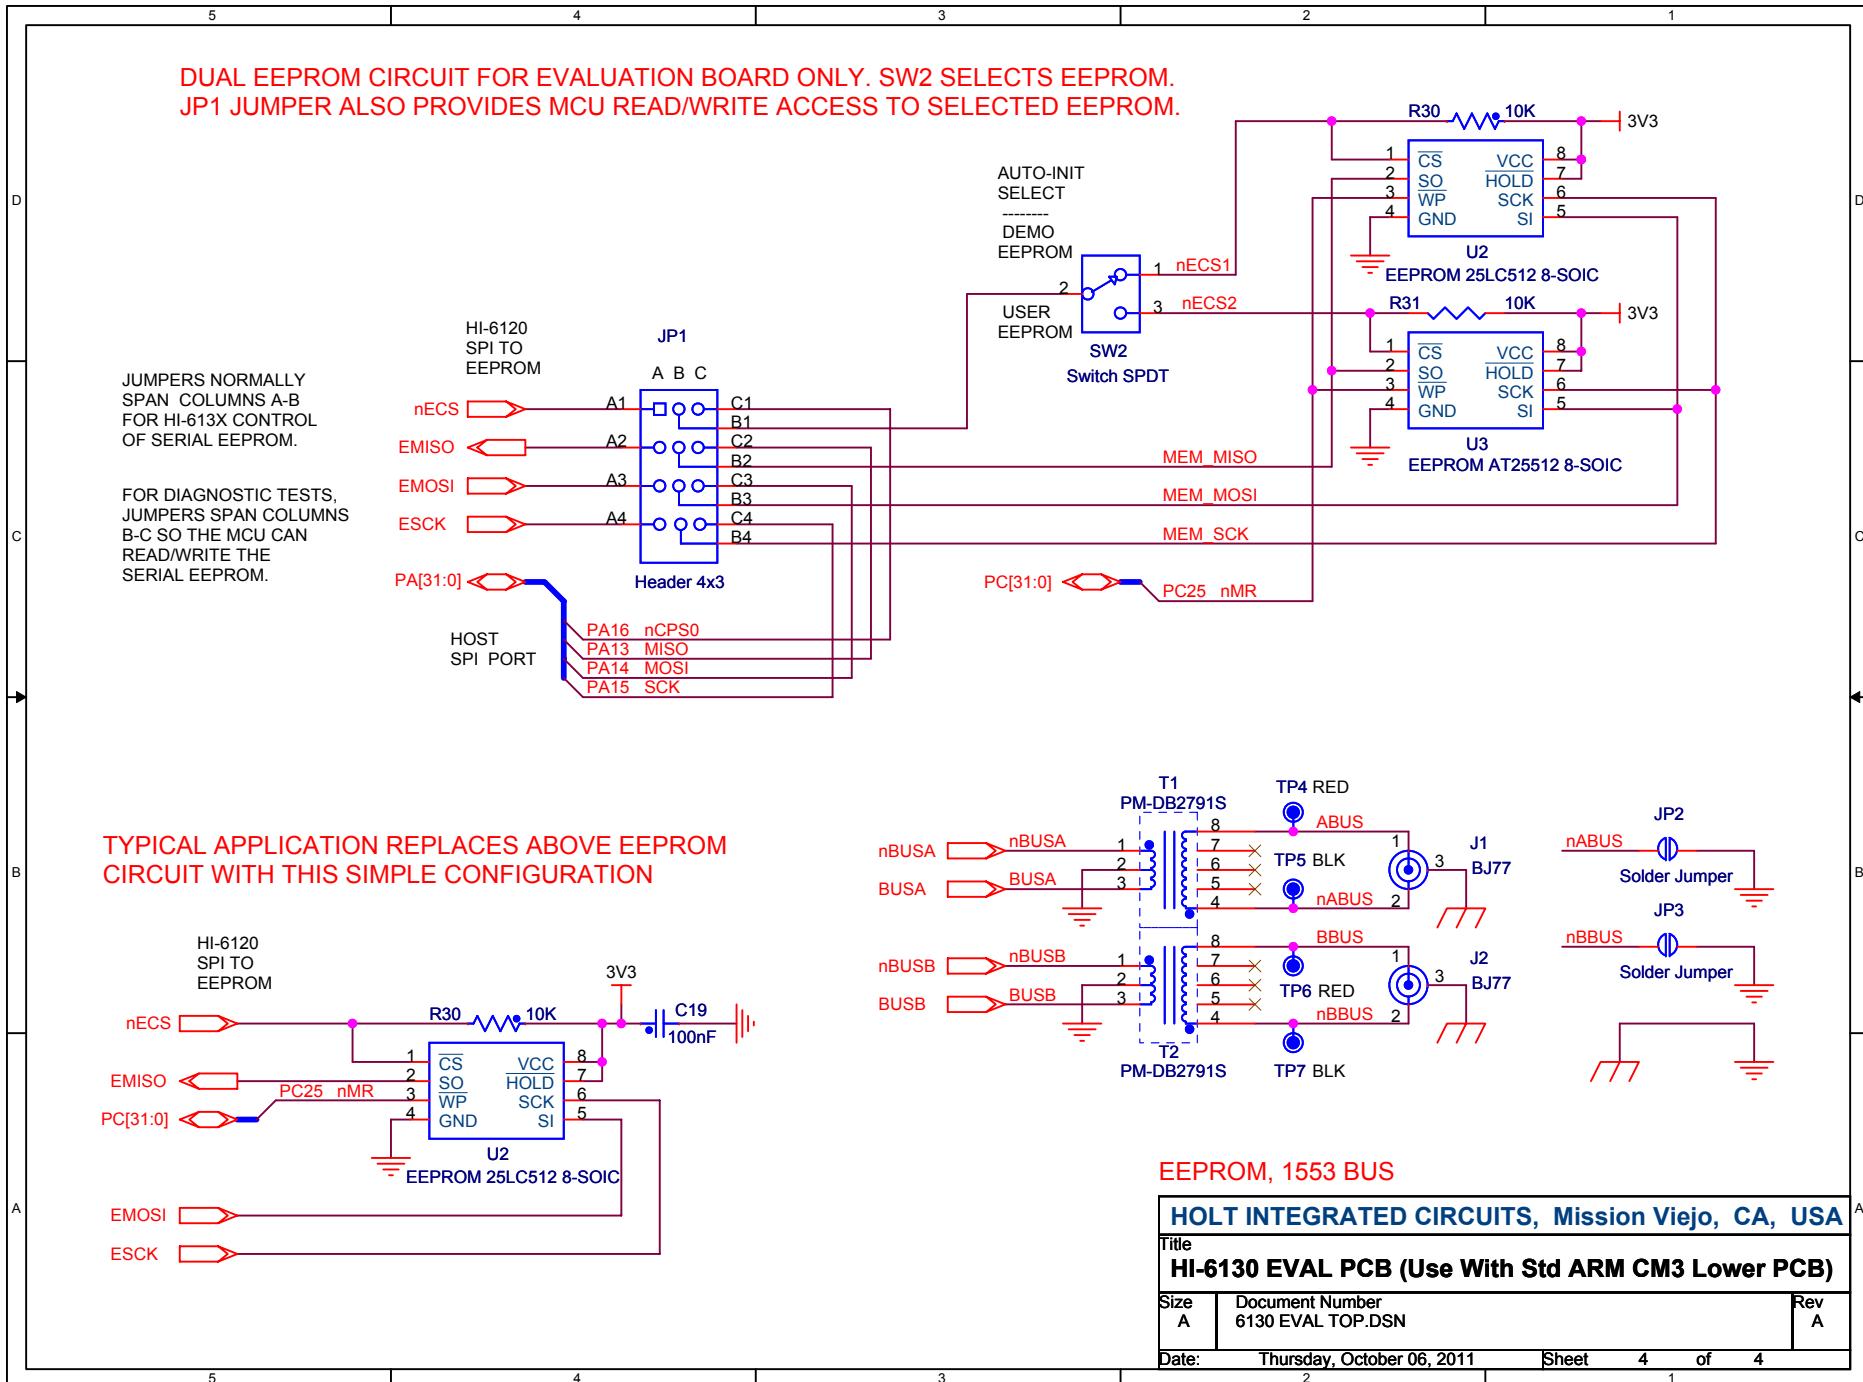

Evaluation board schematic diagrams and bills of material are provided on the following pages

At the end of the document, memory maps show how RAM is allocated.

6130 Demo Memory Map.xls

Notes:

1. All addresses shown are expressed as hexadecimal values.
2. Addressing for HI-6131 uses device internal addresses. Bus addressing for HI-6130 is offset by chip select base address 0x60000000 and microprocessor uses byte addressing so all address offsets are doubled. (The LSB becomes upper/lower byte select for each word.)
3. Memory allocations are shared for undefined and reserved mode code commands, and unimplemented subaddress commands. These commands are grouped by like requirements, and share common RAM resources (bit bucket).
4. For messages needing an odd number of words, an extra "pad" word is added so the next buffer begins at an even address.
5. Subaddresses using circular buffer Mode 1 are followed by a 32-word overrun buffer, in case a 32 data word receive command arrives with just one location remaining before "buffer full" attainment.

6130 Demo Memory Map.xls

Notes:

1. All addresses shown are expressed as hexadecimal values.
2. Addressing for HI-6131 uses device internal addresses. Bus addressing for HI-6130 is offset by chip select base address 0x60000000 and microprocessor uses byte addressing so all address offsets are doubled. (The LSB becomes upper/lower byte select for each word.)
3. Memory allocations are shared for undefined and reserved mode code commands, and unimplemented subaddress commands, These commands are grouped by like requirements, and share common RAM resources (bit bucket).
4. For messages needing an odd number of words, an extra "pad" word is added so the next buffer begins at an even address.
5. Subaddresses using circular buffer Mode 1 are followed by a 32-word overrun buffer, in case a 32 data word receive command arrives with just one location remaining before "buffer full" attainment.

BUS CONTROLLER MEMORY MAP FOR HI-6130 AND HI-6131 APPLICATION DEVELOPMENT BOARD PROGRAM

BC Message Blocks

used in application development kit program

Block Number	Command Type	# Block Words	Block Start Addr	Block End Addr	HI-6130 Bus Addr
1	Tx SA *	8	3E00	3E07	60007C00
2	Tx SA *	8	3E08	3EOF	60007C10
3	Rx SA	8	3E10	3E17	60007C20
4	B Rx SA	8	3E18	3E1F	60007C30

				600036C2	
				600036C4	
				600036C6	
				600036C8	
				600036CA	
				600036CC	
				600036CE	
				600036D0	
				600036D2	
				600036D4	
				600036D6	
				600036D8	
				600036DA	
				600036DC	
				600036DE	

Notes:

1. Command Types: SA = Subaddress cmd, MC = Mode Code cmd, ND = no data, D = with data, B = broadcast.
2. All 4-digit hexadecimal addresses refer to the internal IC address, equal to the address used by HI-6131 SPI.
3. The HI-6130 Bus Address = ARM MCU chip select base addr 0x60000000 + 2 x (feature's IC address)

REVISION HISTORY

Document	Rev	Date	Description of Change
AN-6130	NEW	09/15/11	Initial Release
AN-6130	A	10/06/11	Added RAM memory maps, comment 2 places re: scope triggering Reformatted and updated board schematics and bills of materials.
AN-6130	B	6/15/12	Revise the document and refresh the software project. The new project will only support the HI-6130 (not HI-6131 anymore) but provide an organized project using folders and configurations in the IAR IDE.
AN-6130	C	1/15/13	Update installation instructions for Windows Vista and Windows 7 users.
AN-6130	D	4/14/15	Upgrade demo program software for IAR compatibility and use Simple RT as default demo.
